

# Probing the magnetic field in the GRB / GW 170817 outflow using H.E.S.S. observations

S. Ohm, A. Taylor, H. Ashkar, Q. Piel, F. Schüssler  
for the H.E.S.S. Collaboration,  
X. Rodrigues

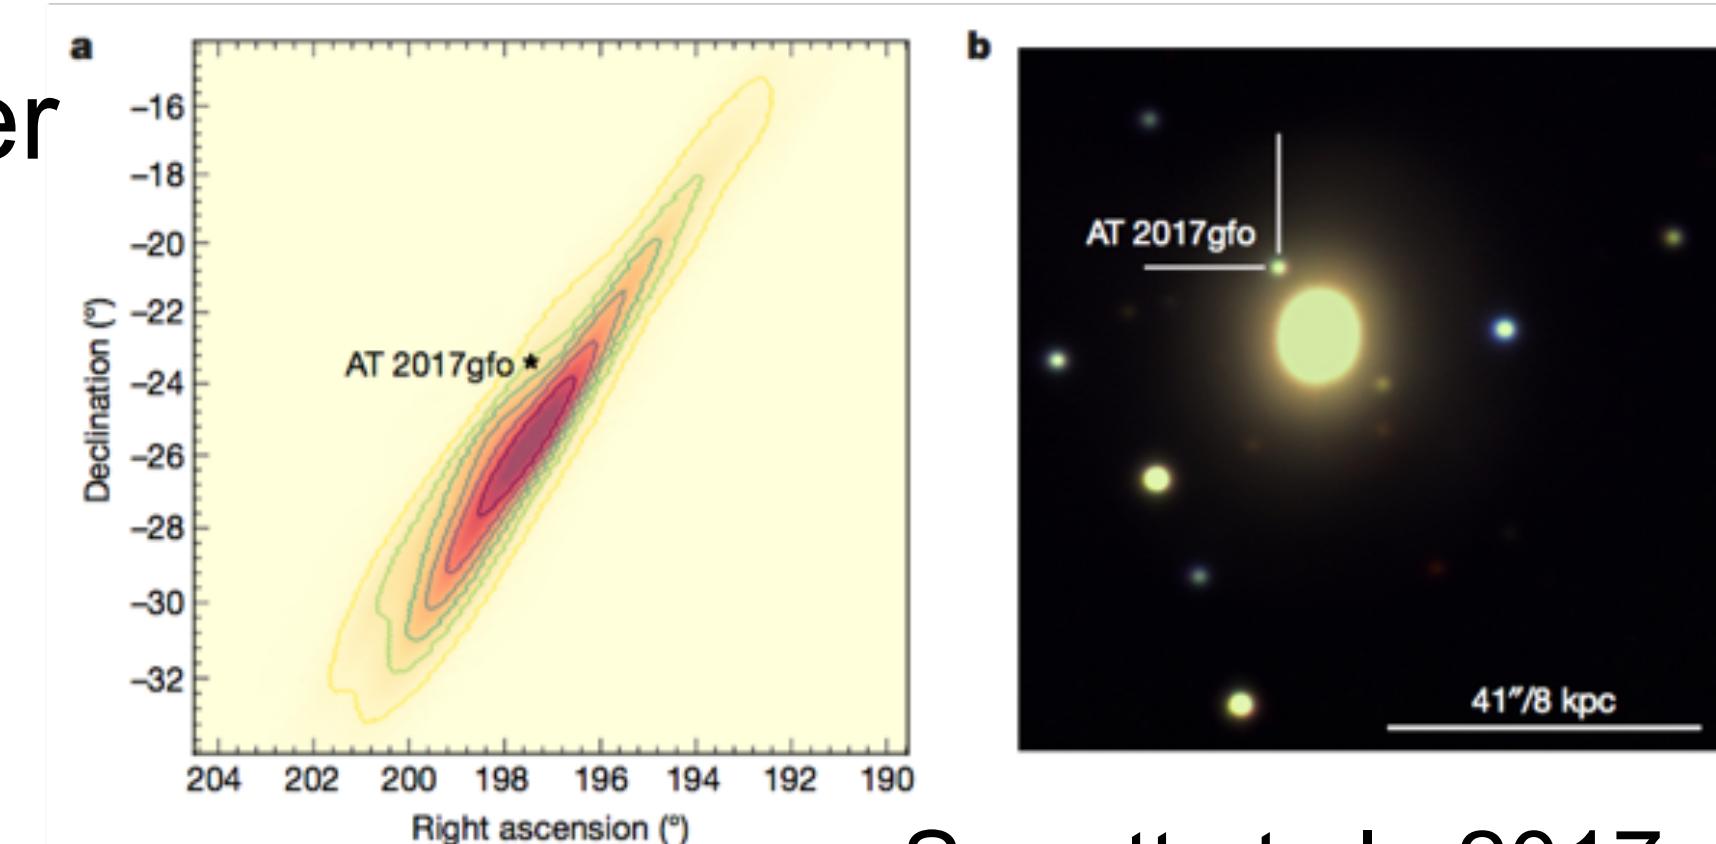

# The electromagnetic counterpart to GW/GRB 170817 - prompt emission

- Origin of prompt emission consistent with
  - NS-NS merger propelled material into intra-merger medium
  - Wide-angle jet inflates ejecta forming a cocoon
  - $\gamma$ -rays produced in shock-breakout
  - r-process elements forged in ejected material hours after merger
- Emission traced in optical and soft  $\gamma$ -rays
- No detection of X-rays or radio until multiple days after merger
- Ejecta properties
  - speeds of 0.1 – 0.3 c → strong shocks
  - ejected mass of few %  $M_{\text{sol}}$  → baryon-rich material
- Particle acceleration and  $\gamma$ -ray / neutrino production?

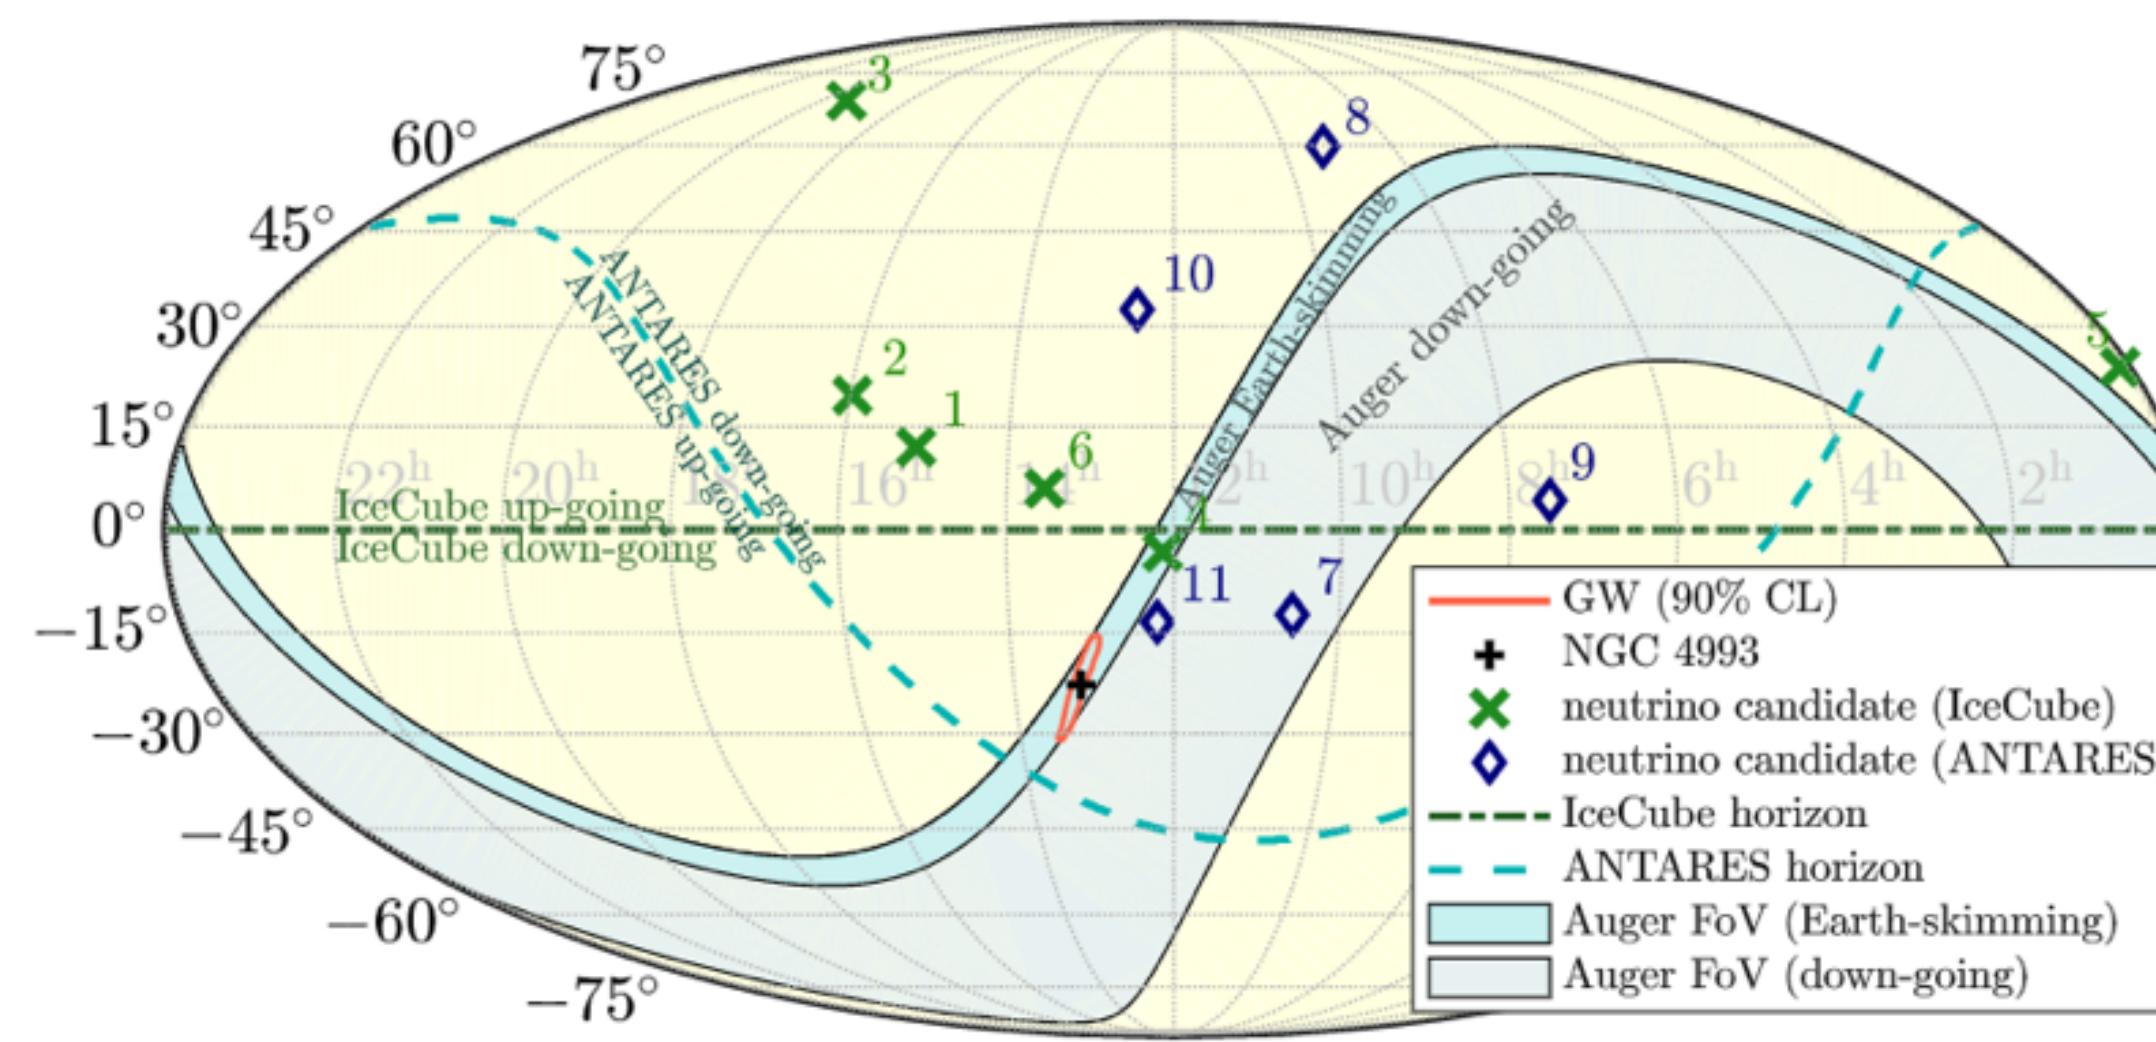

Kasliwal et al., 2017

Smartt et al., 2017

# The ‘early’ follow-up of GW/GRB 170817

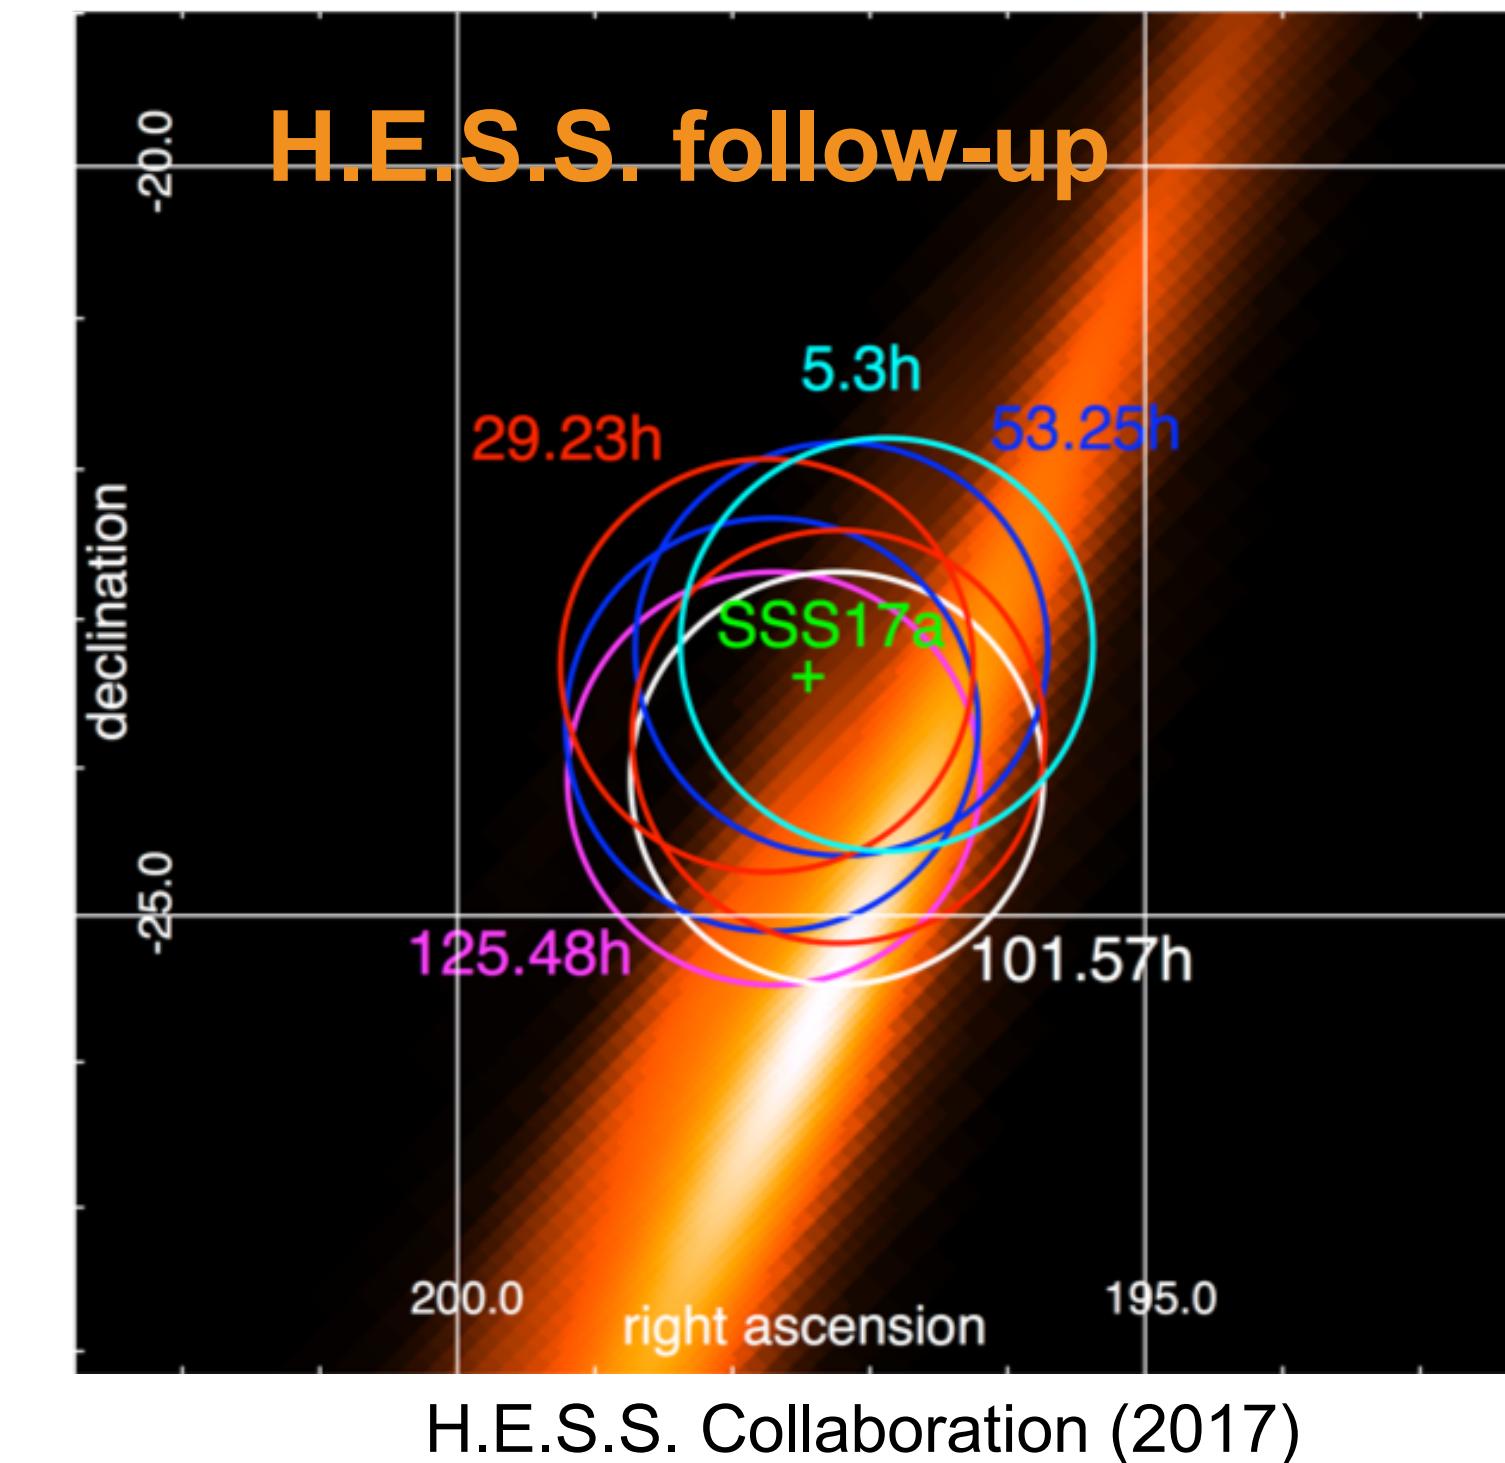

- Neutrinos + UHE cosmic rays
  - ANTARES, IceCube and Auger search did not reveal counterpart within  $\pm 500$ s of merger
  - Neutrino provides direction and gives insight into source environment

LIGO, Virgo, Auger, ANTARES, IceCube, ApJ 850 (2017)

## ■ VHE $\gamma$ rays

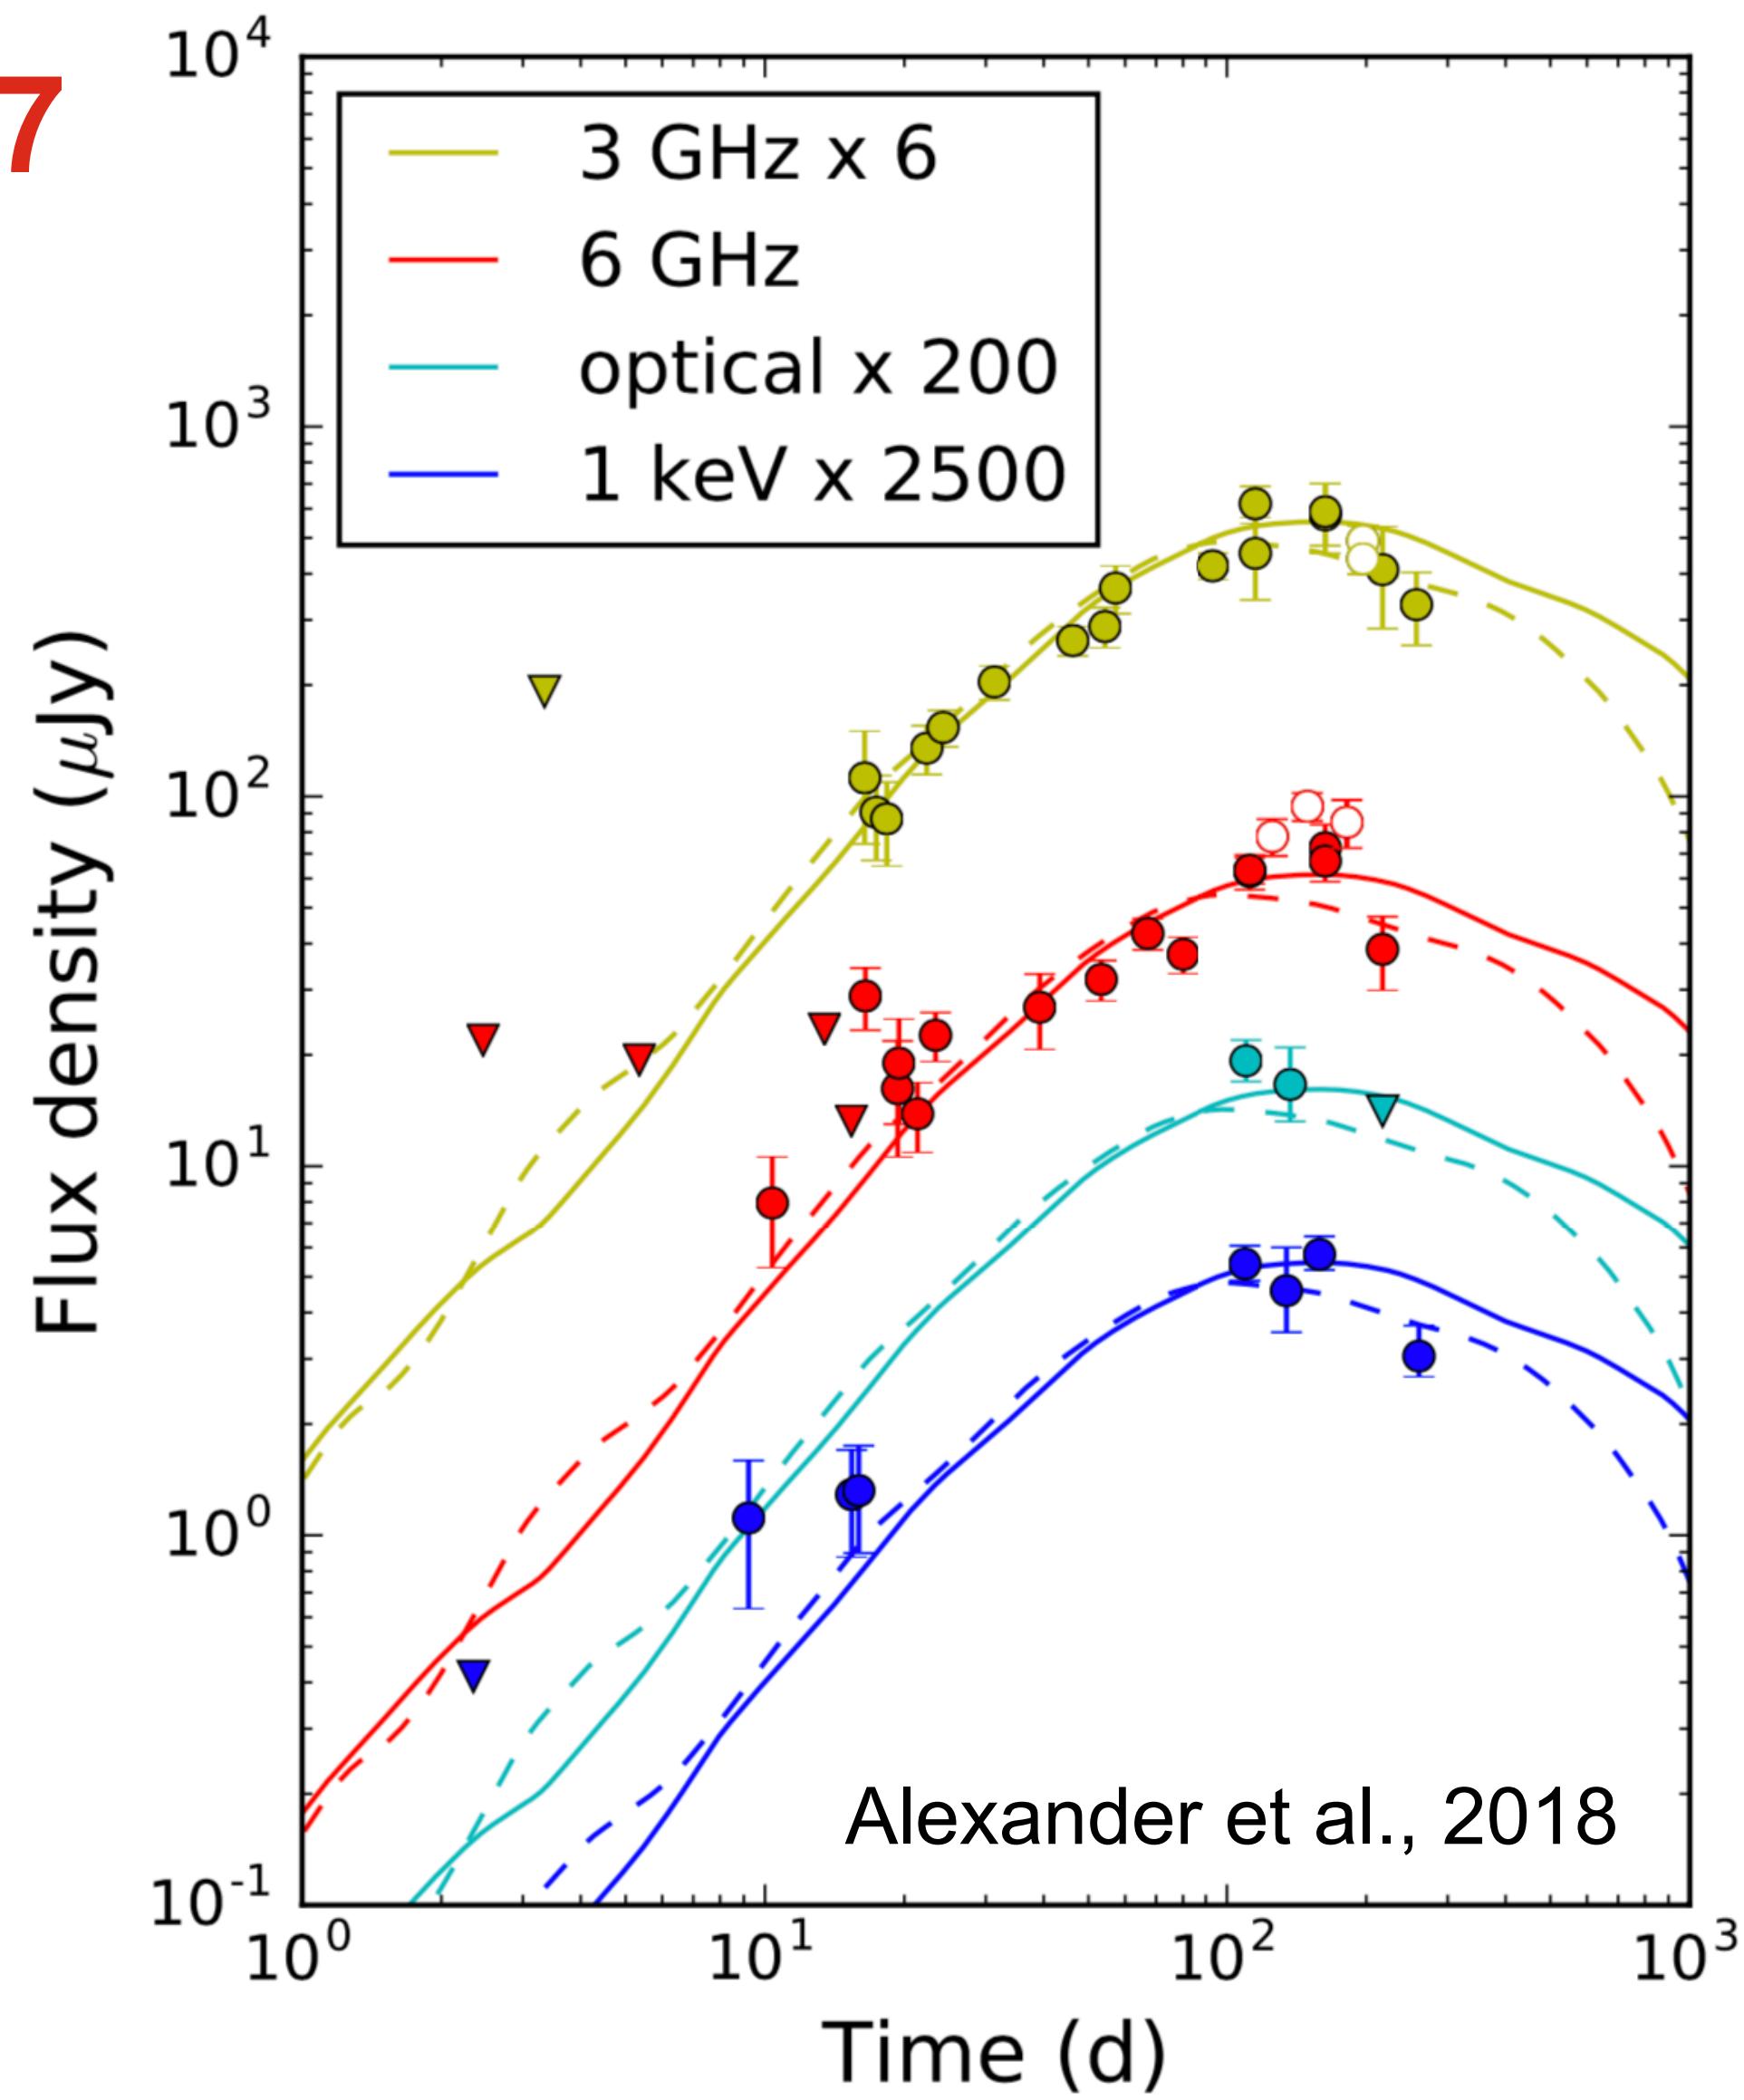

- H.E.S.S. covers uncertainty region 5 hours after event
- 1<sup>st</sup> ground-based pointing telescope to cover NS-NS merger → no detection

H.E.S.S. Collaboration (2017)

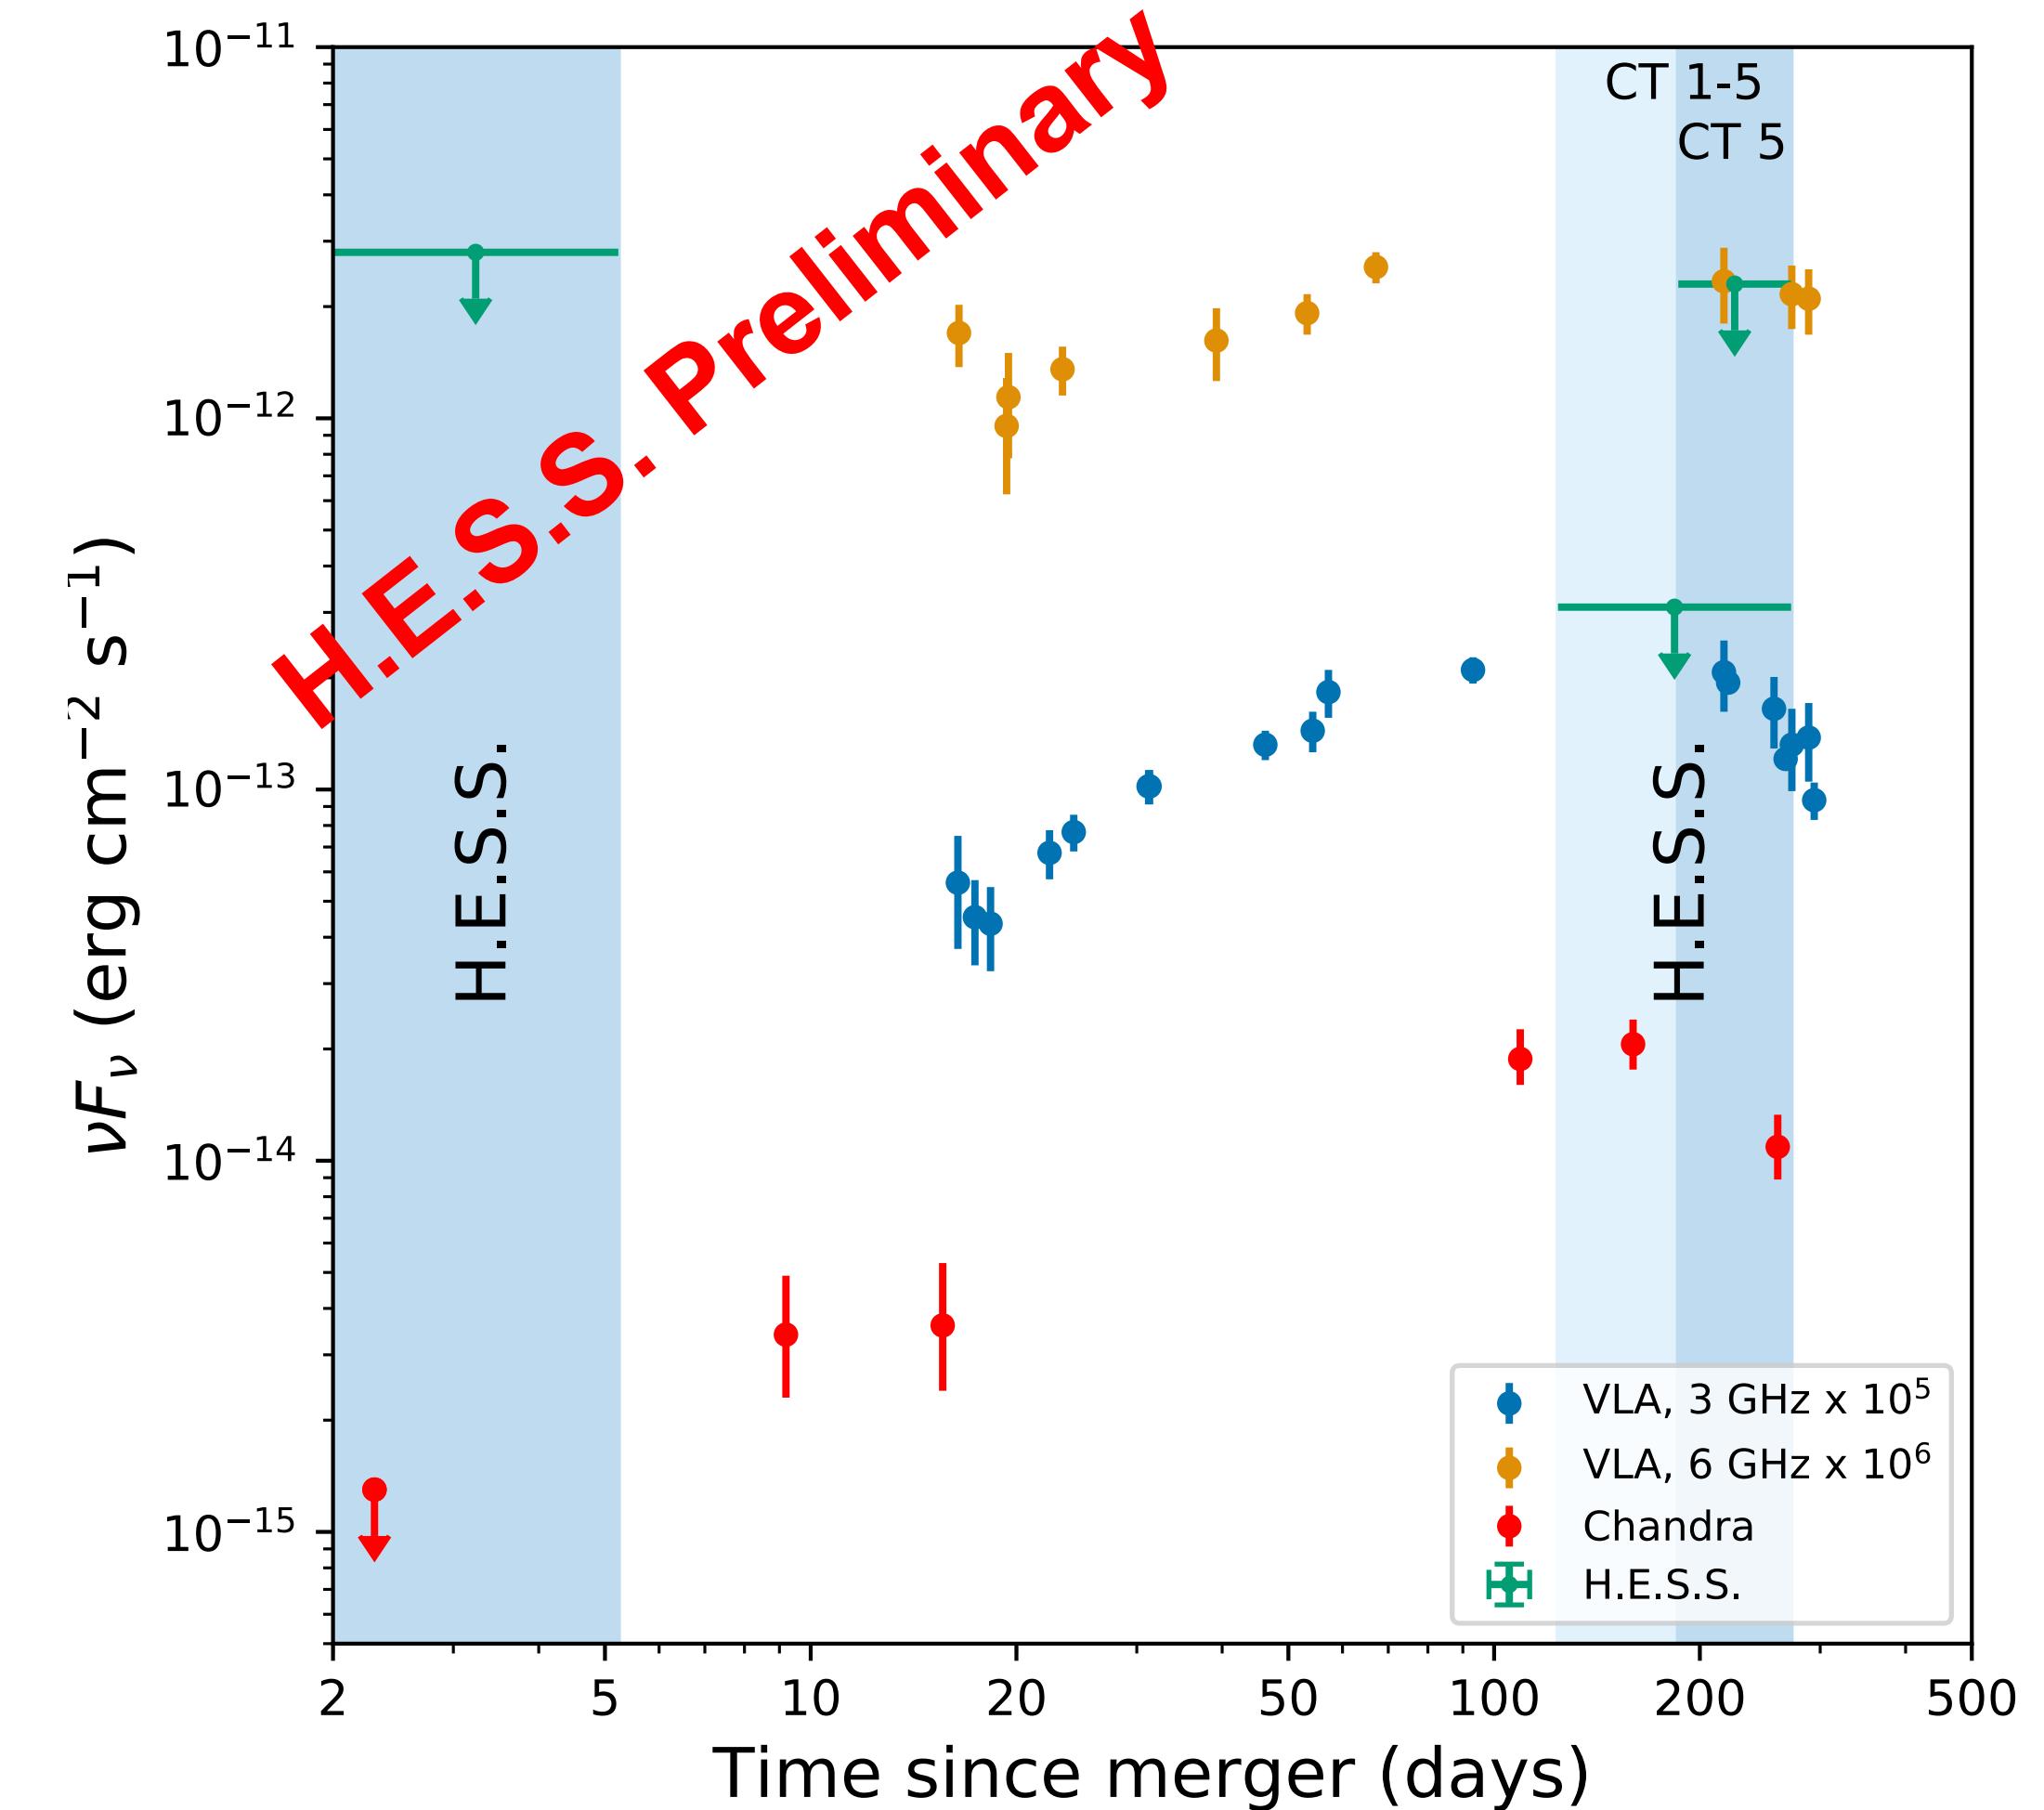

# The ‘late-time’ follow-up of GW/GRB 170817

- Radio and X-rays
  - 10x flux increase in 150 days
  - Efficient electron acceleration synchrotron emission in merger remnants’ magnetic field
  - Plateauing and turnover after 160 days
  - Similar to situation in young supernova remnant
- TeV  $\gamma$  rays?
  - Good conditions for  $\gamma$ -ray production via sync. self-Compton
  - Magnetic field can be estimated based on dynamical / cooling considerations + radio/X-ray
- Instruments like H.E.S.S. can constrain B-field

# H.E.S.S. telescopes and GW / GRB 170817 observations - The ‘late-time’ follow up

- H.E.S.S.
  - operates in 30 GeV – 100 TeV energy range
  - has a field-of-view of  $\sim 10 \text{ deg}^2$
- Data Set
  - pointed observations covering plateau and fading of non-thermal emission (125 – 270 days after merger)
  - 32 hours exposure with CT5 mono
  - 54 hours exposure with CT1-5
- Energy threshold of 130 GeV

# H.E.S.S. results on GW / GRB 170817

- H.E.S.S. results
  - No detection in any of the data sets
  - No detection on month timescales
  - Derive differential and integral upper limits of different data sets
- H.E.S.S. upper limits on the VHE  $\gamma$ -ray flux:

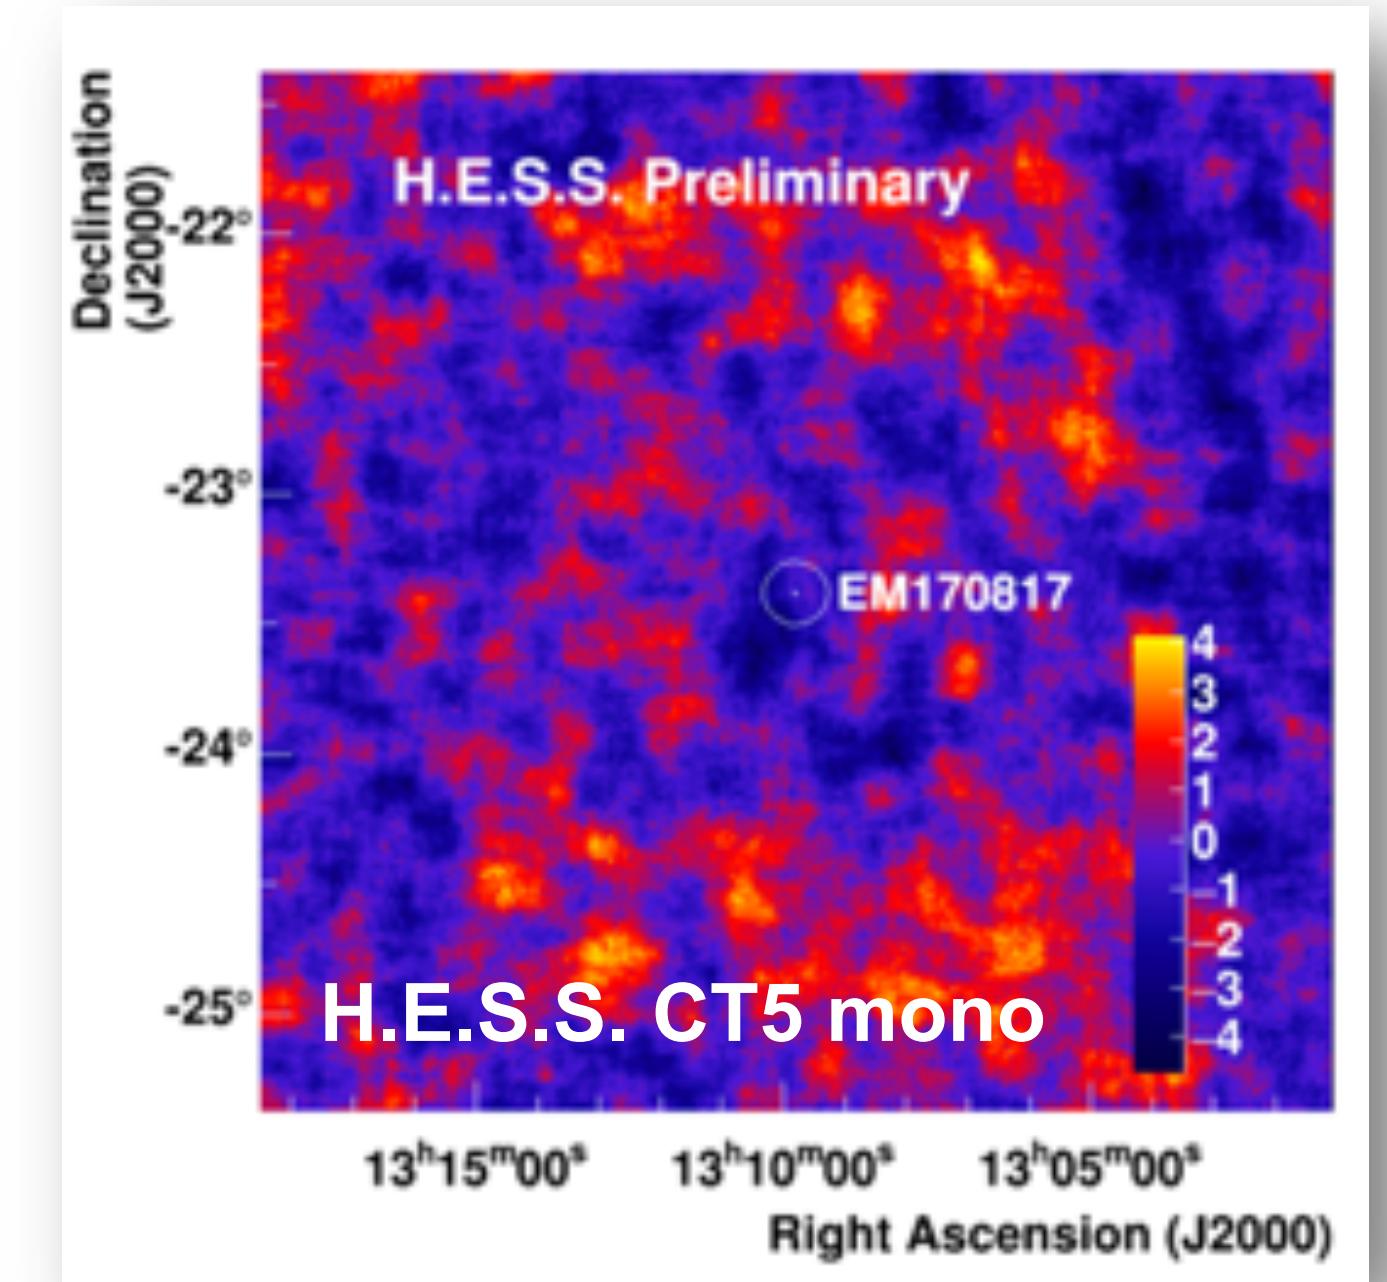

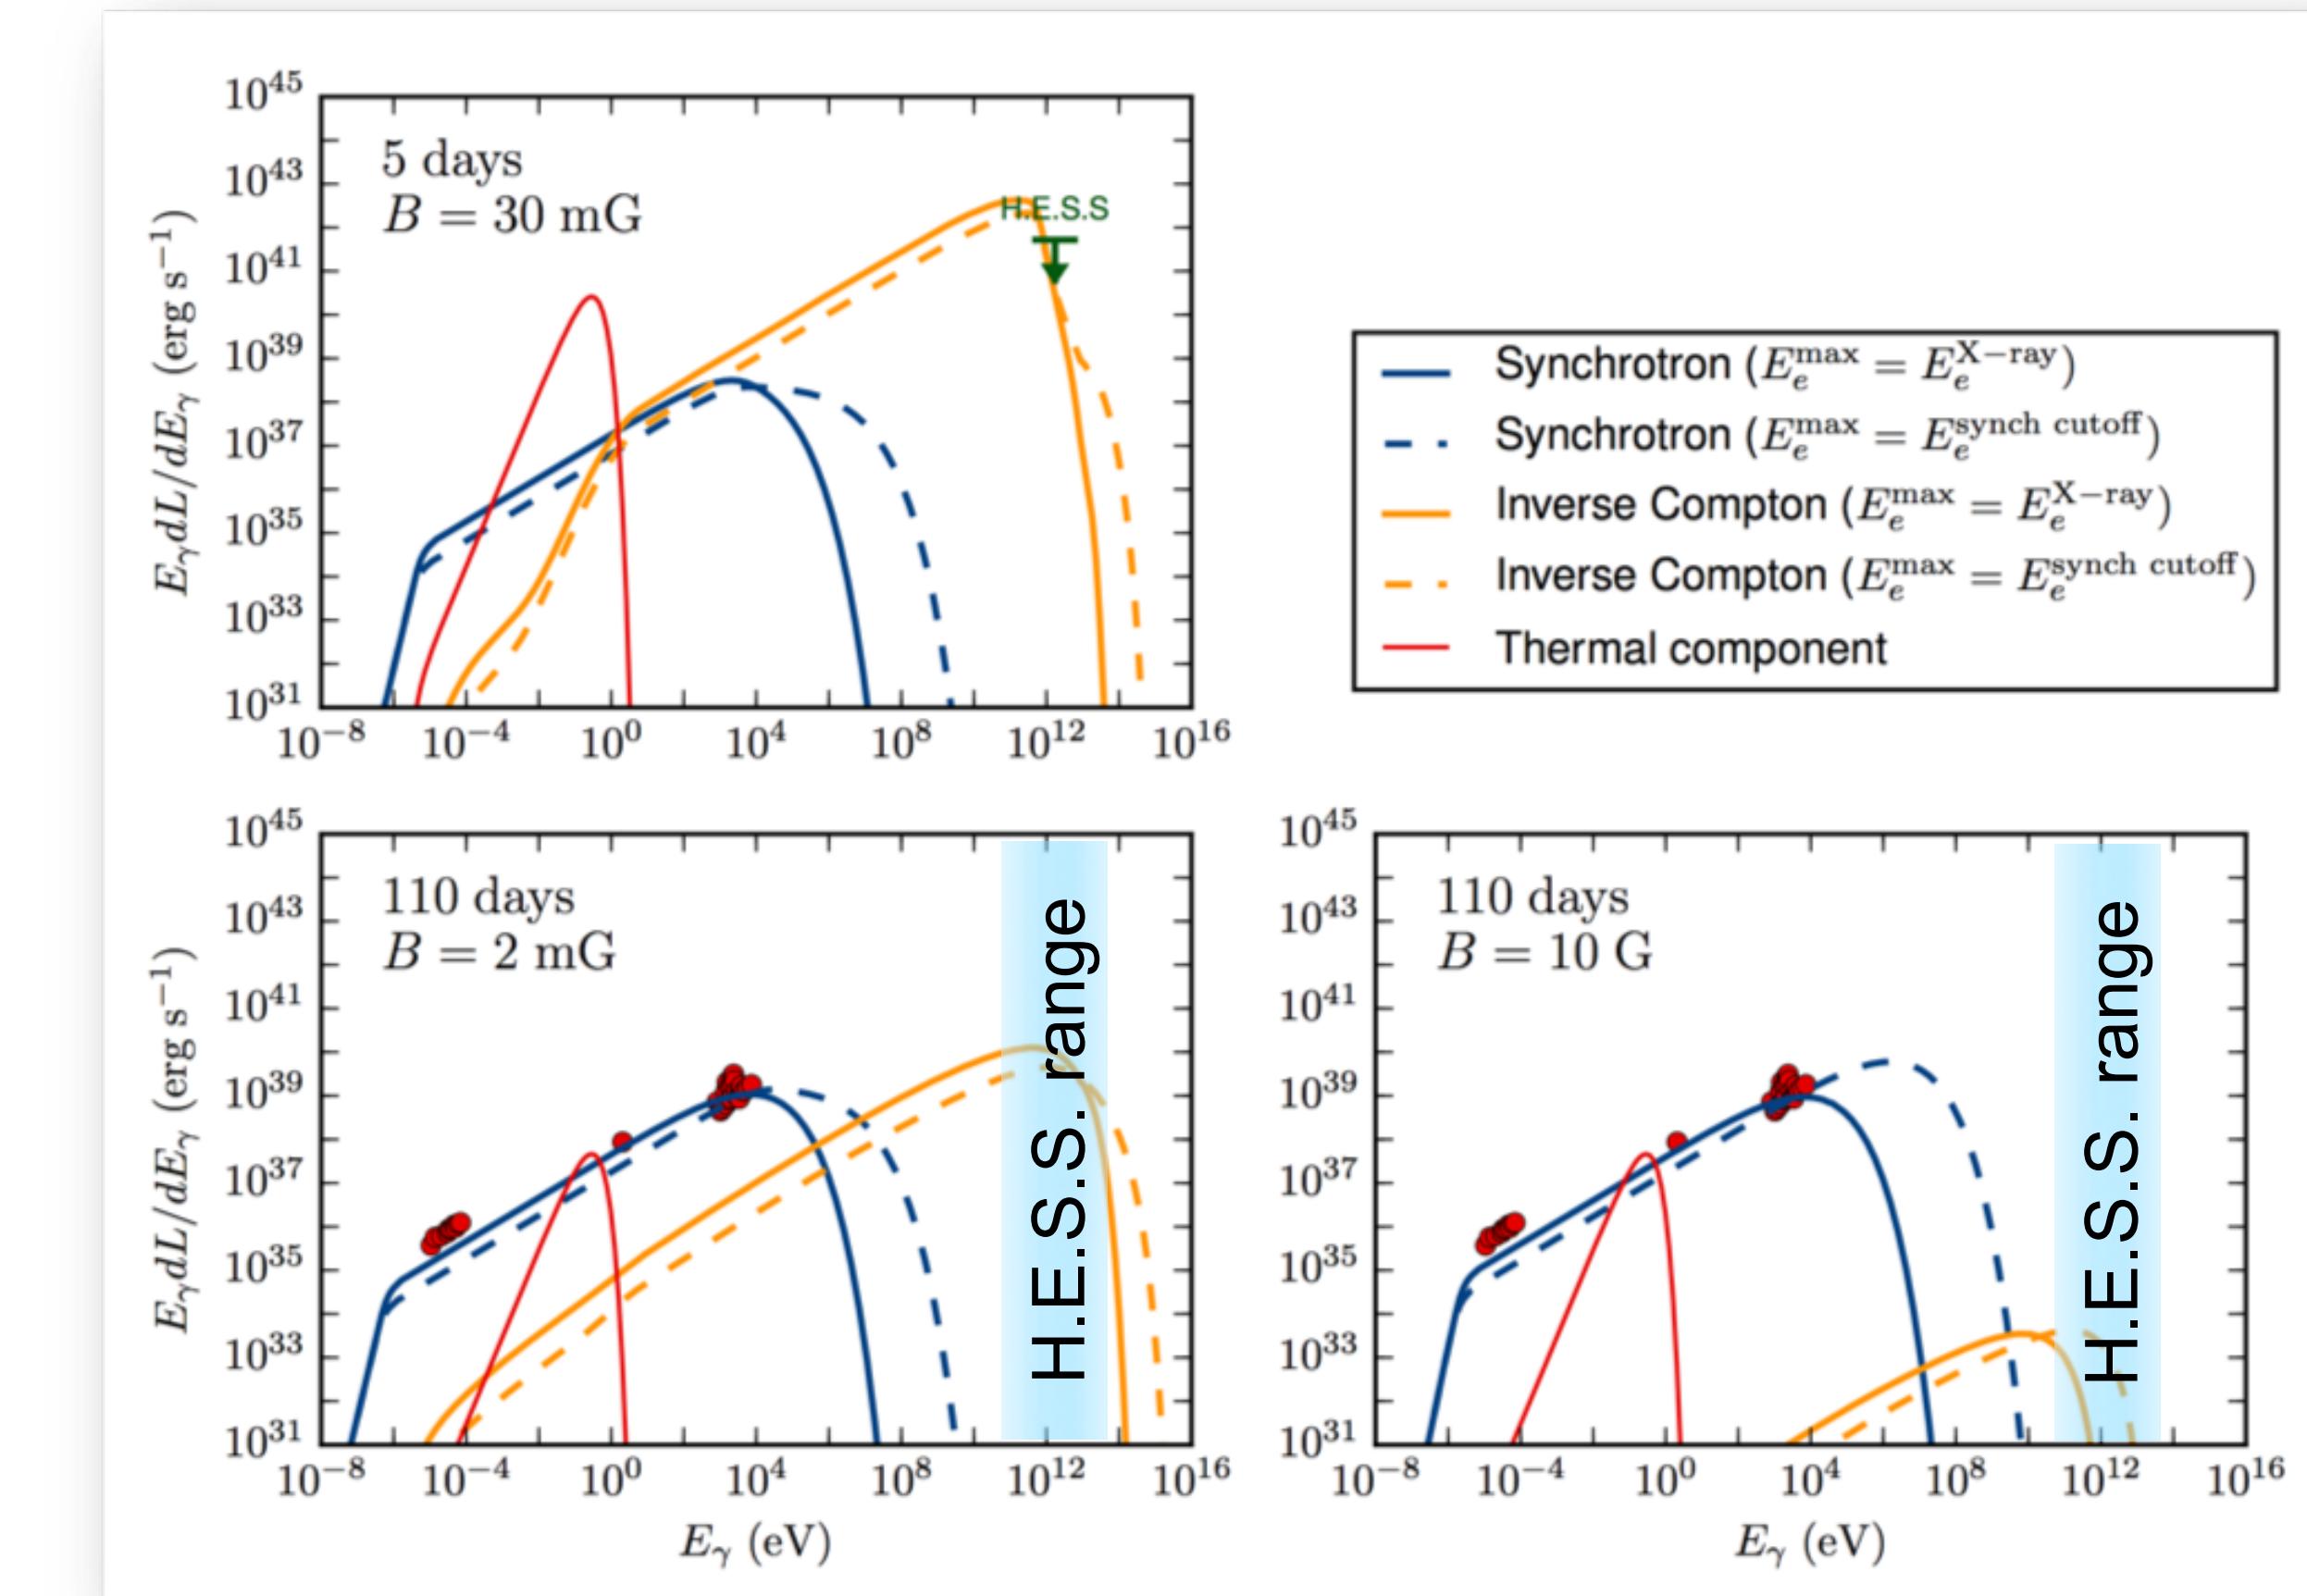

TABLE I: Properties of the H.E.S.S. data sets on GW170817 / GRB 170817A and analysis results.

Data Set	Configuration	$T - T_0$ (days)	Exposure (hours)	$E_{\text{th}}$ GeV	$F(> E_{\text{th}})$ $\text{erg cm}^{-2} \text{s}^{-1}$	$F(1 - 10 \text{ TeV})$ $\text{erg cm}^{-2} \text{s}^{-1}$	Zenith angle °	Reference
I	CT 5	0.22 – 5.23	3.2	270	$< 1.5 \times 10^{-12}$		58	Abdalla et al. [4]
II	CT 1–5	0.22 – 5.23	3.2	560	$< 4.7 \times 10^{-12}$	$< 2.8 \times 10^{-12}$	58	this work
III	CT 5	186 – 272	32.2	130	$< 4.1 \times 10^{-12}$	$< 1.4 \times 10^{-12}$	20	this work
IV	CT 1–5	124 – 272	53.9	130	$< 6.2 \times 10^{-13}$	$< 4.1 \times 10^{-13}$	24	this work

# The H.E.S.S. results in the multiwavelength context

- SED contains information on
    - Energy in non-thermal electrons
    - Magnetic field (evolution) in the ejecta
    - Dynamics of the ejecta
  - Radio & X-rays probe synchrotron emission
    - provides  $N_e * U_B$
    - provide lower limit on  $E_{\max,e}$
    - alone cannot disentangle the two components
  - $\gamma$ -rays probe inverse Compton emission
    - provides  $N_e * U_{\text{rad}}$  ( $U_{\text{rad}} \sim$ fixed via sync self-Compton)
- Radio, X-ray +  $\gamma$ -ray can break ambiguity

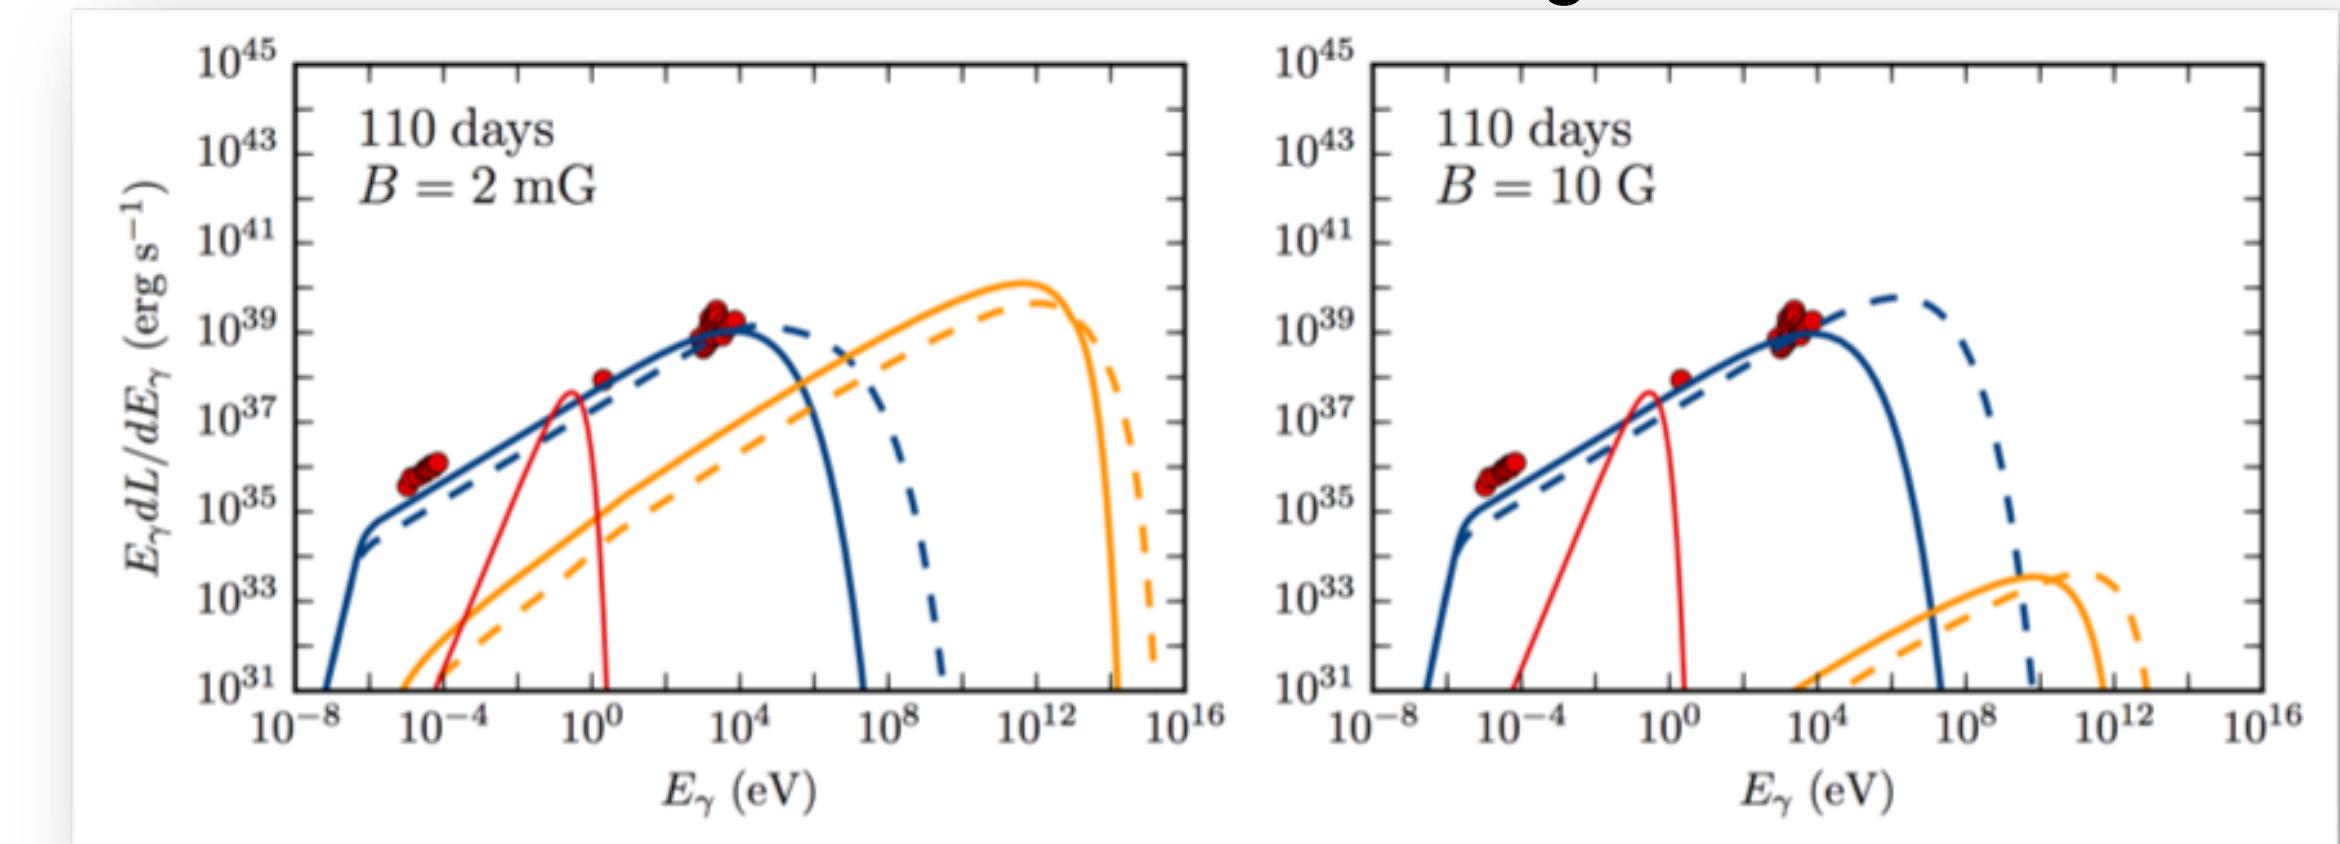

Rodrigues et al., 2018

# Implications for the ejecta in EM170817

Rodrigues et al., 2018

- Radio and X-rays alone imply
  - Lower limit on  $B$  from X-ray energies reached
  - Upper limit on  $B$  from absence of break in X-rays

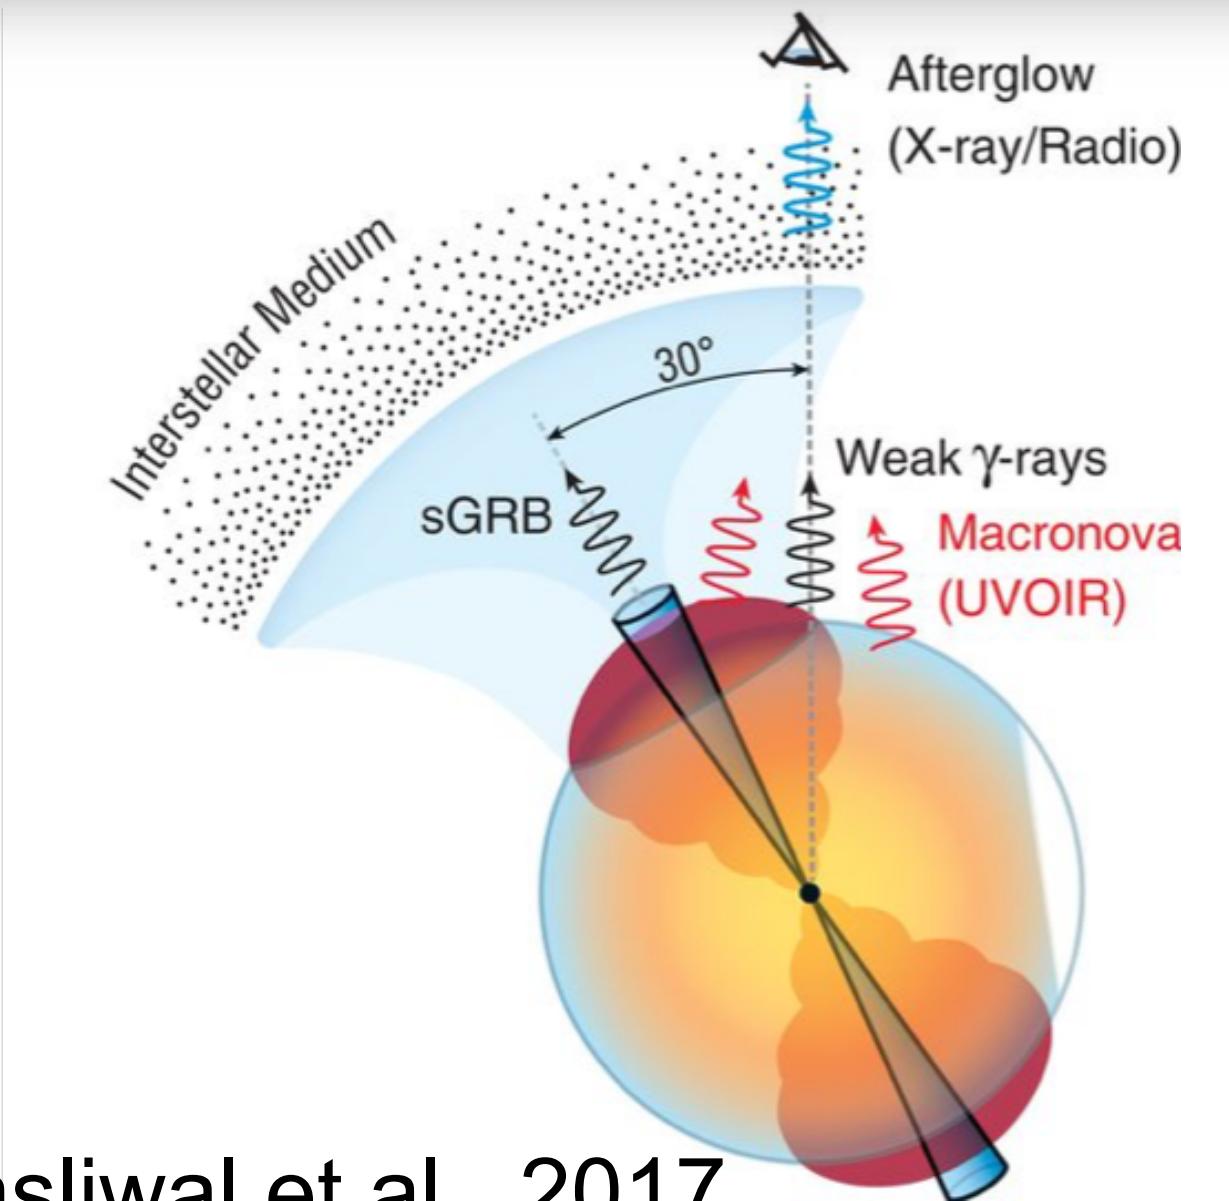

$$0.02 \text{ mG} < B < 2 \text{ mG}$$

- Explore two particle-acceleration scenarios

1. Gamma-ray production in isotropically expanding, non-relativistic outflow ( $\beta=0.2$ )
2. Relativistic jet, seen off-axis ( $\beta=0.94$ ,  $\Gamma=3$ )

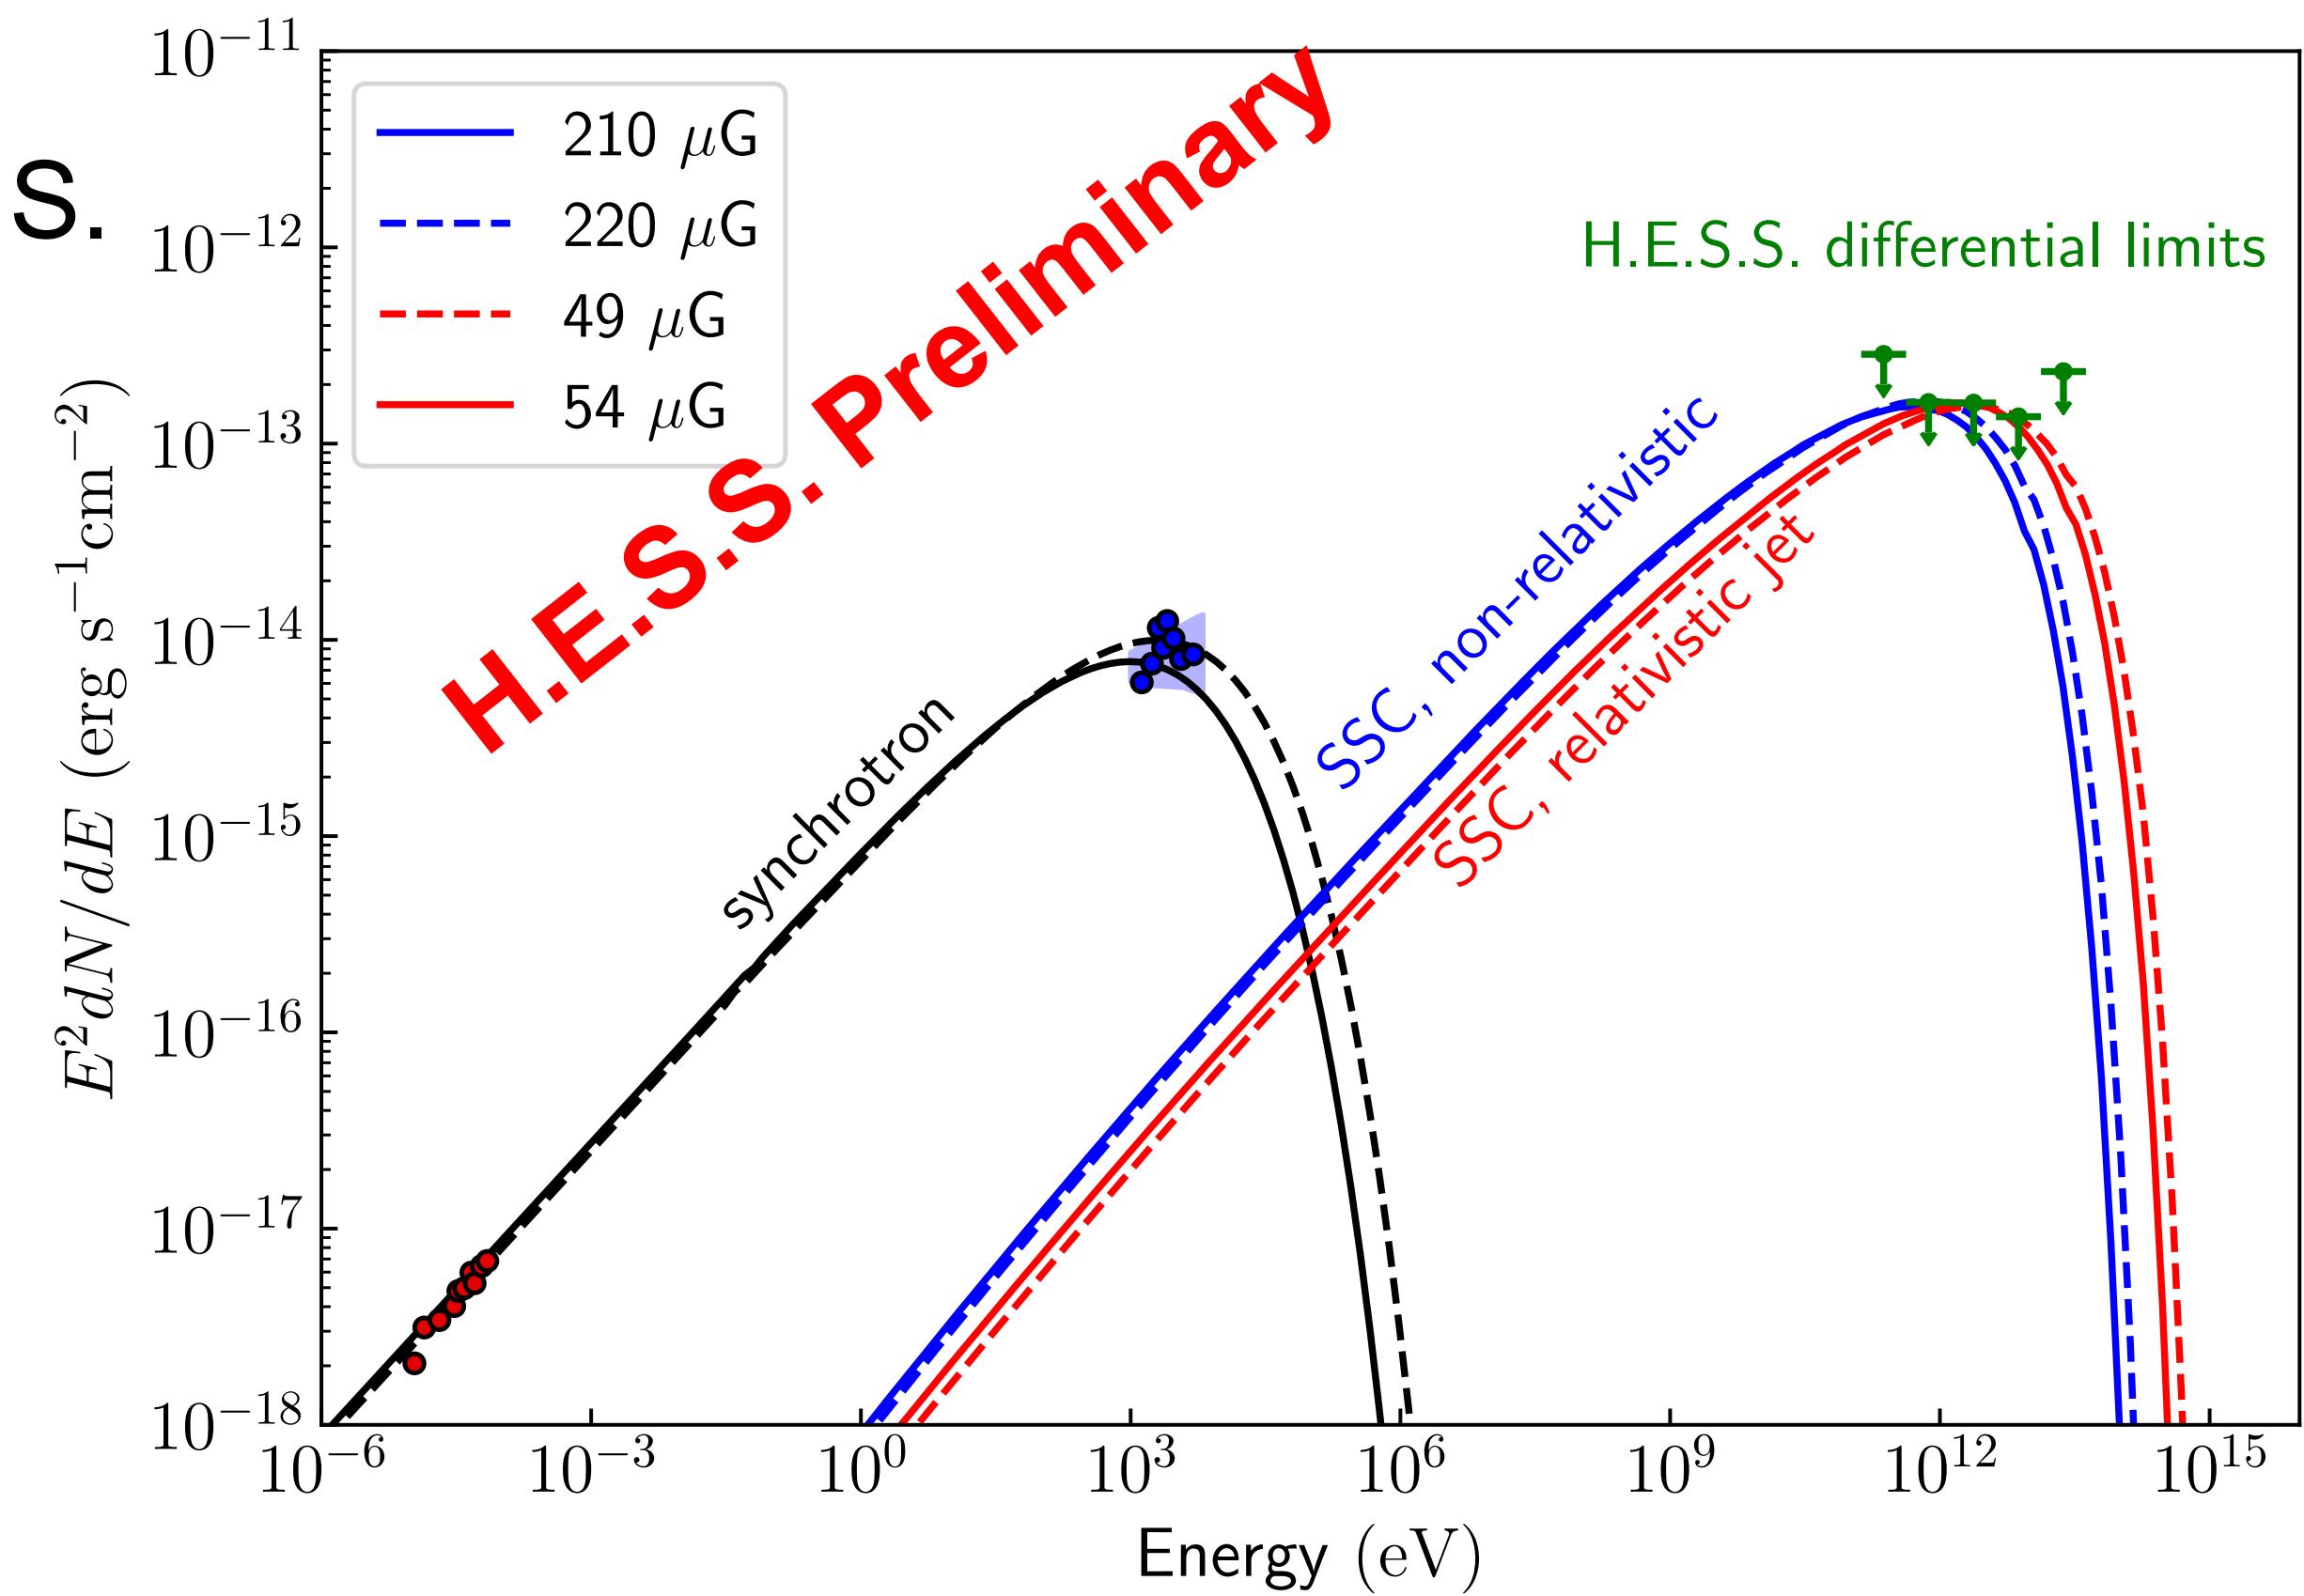

- Calculate expected gamma-ray emission and derive magnetic-field limits

Kasliwal et al., 2017

# Implications for the ejecta in EM170817

- Model SSC emission in the two scenarios at 110 days after the merger
  - Peak of IC component expected in core H.E.S.S. energy range
1. Isotropic, non-relativistic outflow
    - Assuming a filling factor of 1
    - **Constrains B-field to  $\geq 200 \mu\text{G}$**
  2. Relativistic jet
    - Assume filling factor according to implied jet characteristics from radio data  $\rightarrow f = 2.5\text{e-}3$
    - **Constrains B-field to  $\geq 50 \mu\text{G}$**

# Summary

- $\gamma$ -ray measurements of prompt and late-time BNS merger remnants provide important insight into physical conditions in outflows/jets
- H.E.S.S. observed GW/GRB 170817 shortly after BNS trigger and during peak and fading of the non-thermal X-ray and radio emission
- H.E.S.S. doesn't detect inverse Compton component of the SSC emission in deep observations
- Non-detection used to constrain magnetic field in the ejecta in two scenarios
  1. **Spherical, isotropic outflow:**  $\geq 200 \mu\text{G}$
  2. **Off-axis jet:**  $\geq 50 \mu\text{G}$
- Future prospects
  - Eagerly awaiting new bright BNS merger triggers by LIGO/Virgo
  - Non-thermal light-curve will depend on geometry and orientation of jet → need to adjust follow-up strategy
- **Paper in preparation**
