# The Crab Nebula

Max-Planck-Institut für Physik **MAGIC**

36<sup>th</sup> ICRC  
July 29<sup>th</sup>, 2019  
Madison, Wisconsin

## The Crab Nebula

- Pulsar wind nebula
- SED well described by one-zone synchrotron – SSC model
- Brightest persistent source in gamma rays
- ‘Standard Candle’ of VHE gamma-ray astronomy

Juliane van Scherpenberg

# Why search for variability?

Max-Planck-Institut für Physik **MAGIC**

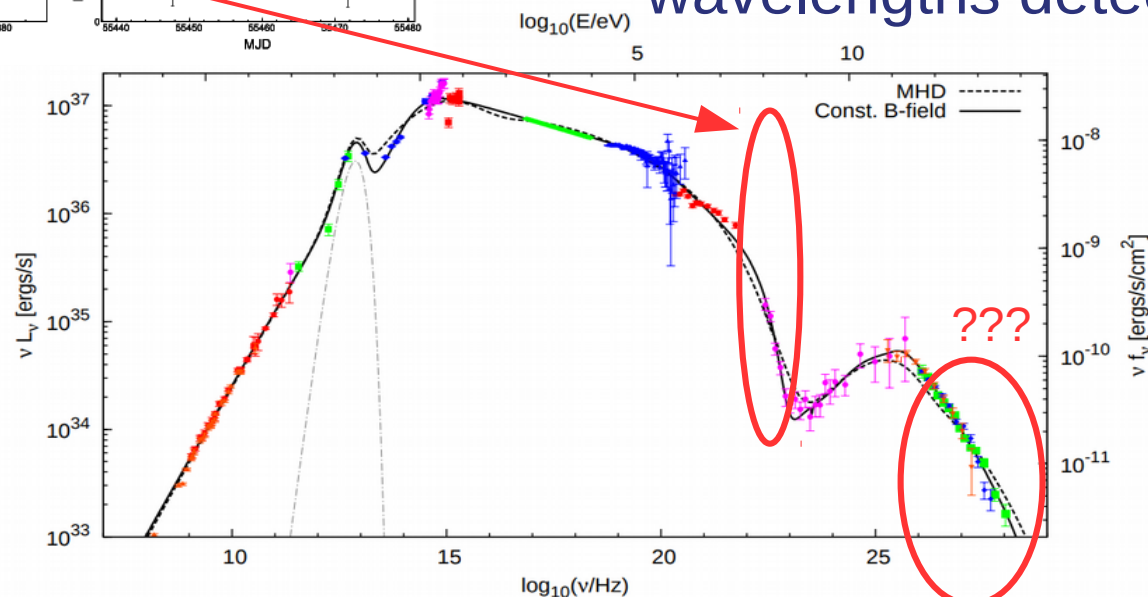

36<sup>th</sup> ICRC  
July 29<sup>th</sup>, 2019  
Madison, Wisconsin

- Observation of flares for first time in 2010 by AGILE & Fermi-LAT (Tavani et al., Abdo et al., 2011)
- Since then  $\sim 1$  flare per year
- Origin not fully understood
- No counterpart at other wavelengths detected

(Abdo et al. 2011)

Meyer et al. (2010)

Juliane van Scherpenberg

# Flares in the Crab Nebula

Max-Planck-Institut für Physik **MAGIC**

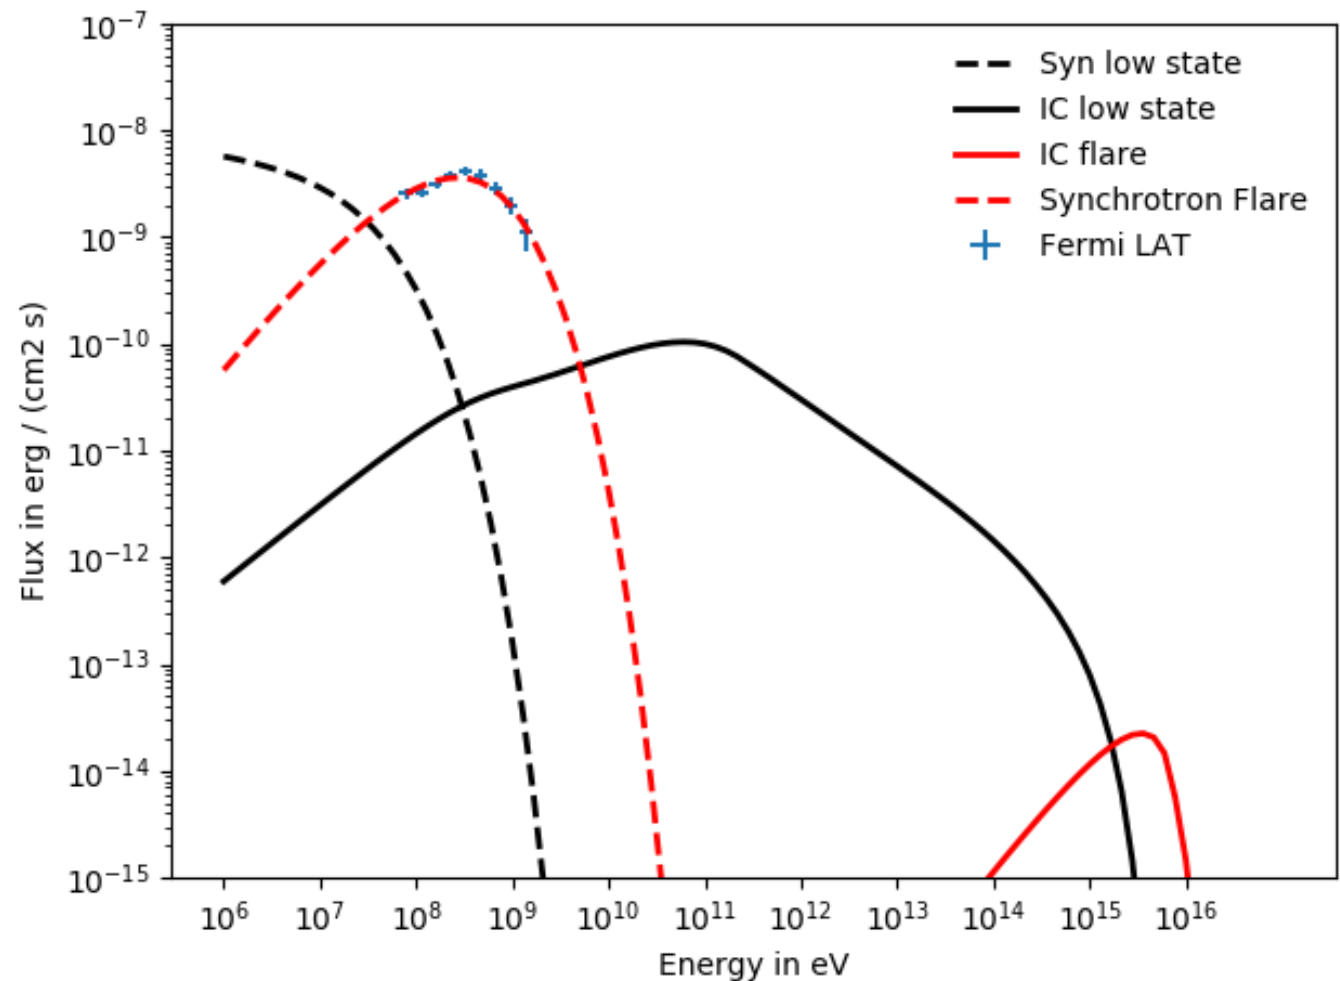

36<sup>th</sup> ICRC  
July 29<sup>th</sup>, 2019  
Madison, Wisconsin

Brightest Fermi flare:  
April 2011  
(arxiv:1112.1979)

Using *naima*-package:  
Fermi-LAT data  
approximated by  
introducing additional e<sup>-</sup>-  
population

With standard Crab  
nebula parameters:  
 $B \approx 125 \mu\text{G}$   
 $R \approx 2 \text{ pc}$

Inverse Compton  
component around  $\sim \text{PeV}$

# Flares in the Crab Nebula

Max-Planck-Institut für Physik **MAGIC**

36<sup>th</sup> ICRC  
July 29<sup>th</sup>, 2019  
Madison, Wisconsin

Standard Crab nebula  
parameters:

$$B_{\text{Crab}} \approx 125 \mu\text{G}$$

$$R_{\text{Crab}} \approx 2 \text{ pc}$$

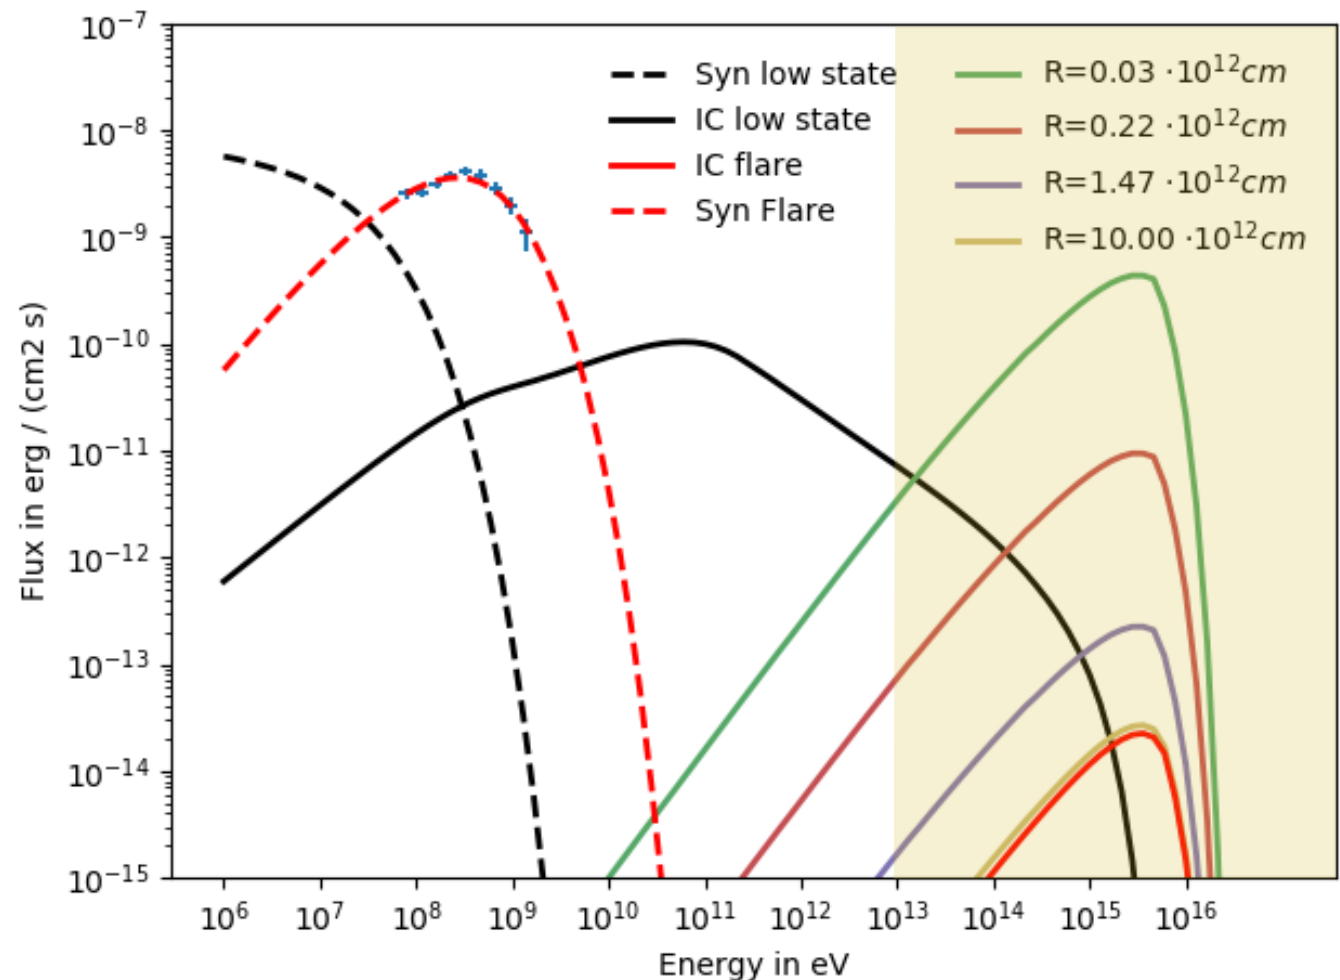

Short timescale of flares  
→ emission region  $\ll R_{\text{Crab}}$

$$R_{\text{flare}} \sim 10^{-4} \text{ pc} \sim 10^{14} \text{ cm}$$

(plus locally strongly  
enhanced magnetic fields,  
Doppler boosting)

IC counterpart would  
appear in very high TeV  
energies

Difficulty: For low state Crab at 10 TeV  $< 10$  Events per hour per  $1 \text{ km}^2$  expected  
(at 300 GeV  $\sim 1$  Event per second)

# The MAGIC Telescopes

Max-Planck-Institut für Physik **MAGIC**

36<sup>th</sup> ICRC  
July 29<sup>th</sup>, 2019  
Madison, Wisconsin

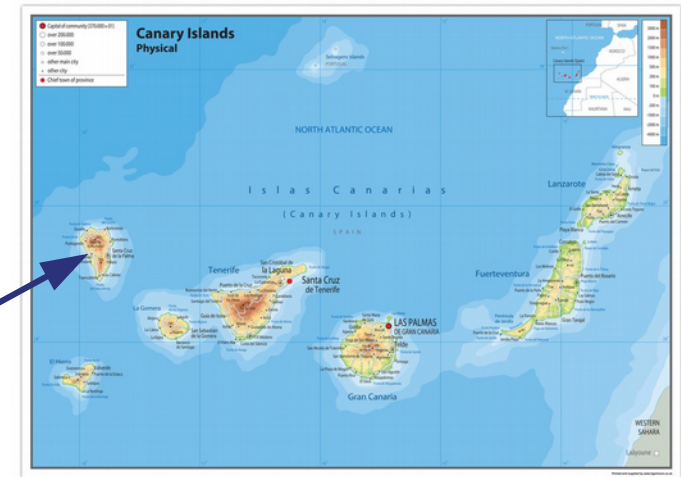

- Two Imaging Air Cherenkov Telescopes (IACTs) working in stereoscopic mode
- Located at Roque de los Muchachos Observatory on La Palma at 2200m a.s.l.

**MAGIC 1**

**Counting  
House**

**MAGIC 2**

- Energy range from 30 GeV to 100 TeV
- Energy resolution between 15% and 25%
- Field of view 3.5°
- Sensitivity of ~0.5% Crab Nebula Flux in 50hrs above ~400GeV
- Typical effective area:  $10^3 - 10^5 \text{ m}^2$

# VLZA Observations with the MAGIC Telescopes

Max-Planck-Institut für Physik **MAGIC**

36<sup>th</sup> ICRC  
July 29<sup>th</sup>, 2019  
Madison, Wisconsin

**VLZA = Very Large Zenith Angles:  $70^\circ - 80^\circ$**

A new efficient tool to study the highest energy gamma rays

Larger distance from the air shower  $\rightarrow$  boost in effective area to  $> 1\text{km}^2$

# Multi-year Light Curve

Max-Planck-Institut für Physik **MAGIC**

36<sup>th</sup> ICRC  
July 29<sup>th</sup>, 2019  
Madison, Wisconsin

- Data taken between December 2014 and April 2018
- Zenith Angles: 70° - 80°
- ~ 50 hours of good quality data

## Light Curve:

- Energy threshold:  
10 TeV
- Monthly bins

# Multi-year Light Curve

Max-Planck-Institut für Physik **MAGIC**

36<sup>th</sup> ICRC  
July 29<sup>th</sup>, 2019  
Madison, Wisconsin

## Light Curve:

- Energy threshold: 10 TeV
- Monthly bins

## Constant Fit:

- Poisson statistics
- Maximum likelihood

## Goodness of Fit:

- Simulation of equivalent LCs
- Compute logL for each
- P-value from CDF of simulated logL-values

## Fit:

- $F_{\text{fit}} = (0.25 \pm 0.03) \cdot 10^{-12} \text{ cm}^{-2} \text{ s}^{-1}$
- $p = 0.99$        $\chi^2/\text{Ndf} = 21.27/20$

Data in good agreement with a constant fit → No evidence for variability

# Upper Limits on Variability

Max-Planck-Institut für Physik **MAGIC**

36<sup>th</sup> ICRC  
July 29<sup>th</sup>, 2019  
Madison, Wisconsin

Common quantification of variability:

→ Fractional Variation

$$F_{var} = \frac{\sqrt{\sigma^2 - \delta^2}}{\langle f \rangle}$$

$$\sigma^2 = \frac{1}{N} \sum_{i=1}^N (f_i - \langle f \rangle)^2$$

Mean squared  
deviation from fit

$$\delta^2 = \frac{1}{N} \sum_{i=1}^N \delta_i^2$$

Mean squared  
uncertainty of data  
(only statistical here)

$\langle f \rangle$

Fitted flux

- Same set of simulated light curves as for goodness of fit estimation
- Calculate  $F_{var}$  for each
- From cumulative distribution obtain upper limits

99.7% upper limit for variability above 10 TeV:  $F_{var} = 1.86$  (preliminary)

# Sensitivity to fluctuations

Max-Planck-Institut für Physik **MAGIC**

36<sup>th</sup> ICRC  
July 29<sup>th</sup>, 2019  
Madison, Wisconsin

Which scale of fluctuations in the Crab nebula flux could we detect ?

- Simulations of light curves as before, but allowing flux to fluctuate within certain range  $[-s, s]$ 
  - $f = f_{\text{fit}} + \Delta f \cdot f_{\text{fit}}$ , where  $\Delta f$  drawn from uniform distribution between  $[\max(-1, -s), s]$
- Produce distribution of fractional variation  $F_{\text{var}}$
- Repeat for different scales
- Calculate probability for  $F_{\text{var}}$  distribution to overlap with  $F_{\text{var}}$  distribution from constant flux assumption

$$P_{\text{overlap}} \leq 0.3\% \text{ for } s \geq 2.25$$

Sensitive to fluctuations on top of Crab nebula flux above 10 TeV within at least  $2.25 \cdot f_{\text{fit}} = 0.56 \cdot 10^{-12} \text{ cm}^{-2} \text{ s}^{-1}$  (preliminary)

# Sensitivity to fluctuations

Max-Planck-Institut für Physik **MAGIC**

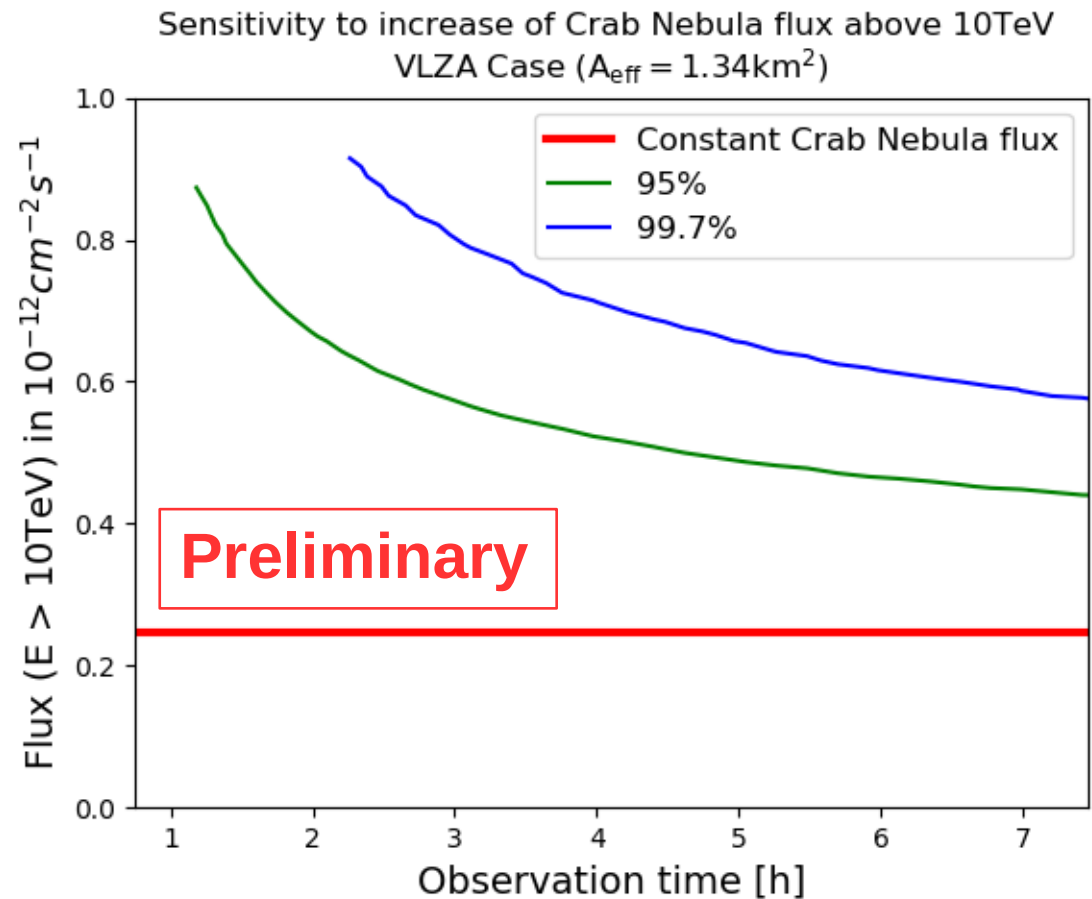

36<sup>th</sup> ICRC  
July 29<sup>th</sup>, 2019  
Madison, Wisconsin

Which scale of flux increase could we detect within a given time?

Compare distribution of expected number of On-source counts for certain flux increase to expectation for nominal flux above 10 TeV

- For different flux increases
- For different exposures

Note: 1h per night at VLZA  
→ 5 nights for 5 hours of observation time

# Summary & Outlook

Max-Planck-Institut für Physik

MAGIC

36<sup>th</sup> ICRC  
July 29<sup>th</sup>, 2019  
Madison, Wisconsin

- VLZA observations open window for MAGIC towards the highest TeV energies
- Technique and analysis well under control
- No variability found in 3.5 year light curve  
→ Crab is still our “standard candle”
- Sensitive to overall fluctuations of within  $2.25 \cdot F_{\text{crab}}$
- Sensitive to flares with factor  $\sim 3$  flux increase in  $< 4$  hours
- Still exploring possibilities of improving VLZA analysis to increase sensitivity
- Large and interesting data set → room for more detailed studies
- Will keep monitoring Crab nebula at VLZA
- Hope for Crab to be nice to us and bless us with a BIG flare!
